Reactor Antineutrino 5 MeV Bump

[RENO, arXiv:1511.05849]

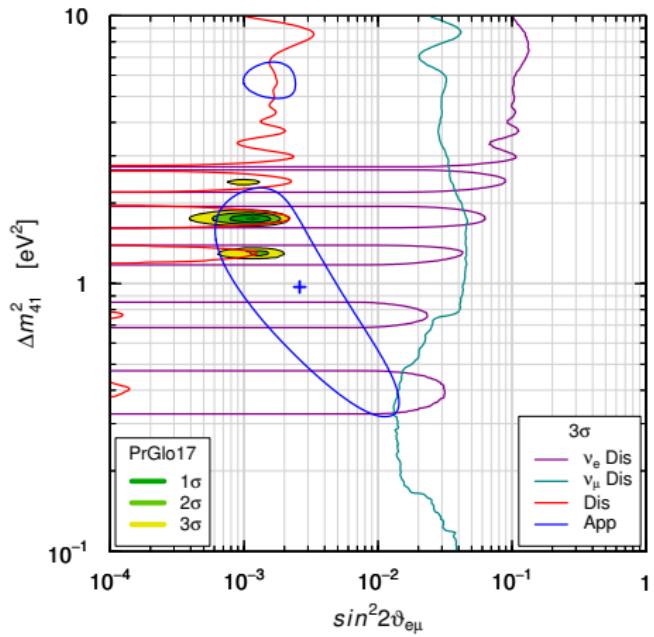

[Double Chooz, arXiv:1406.7763]

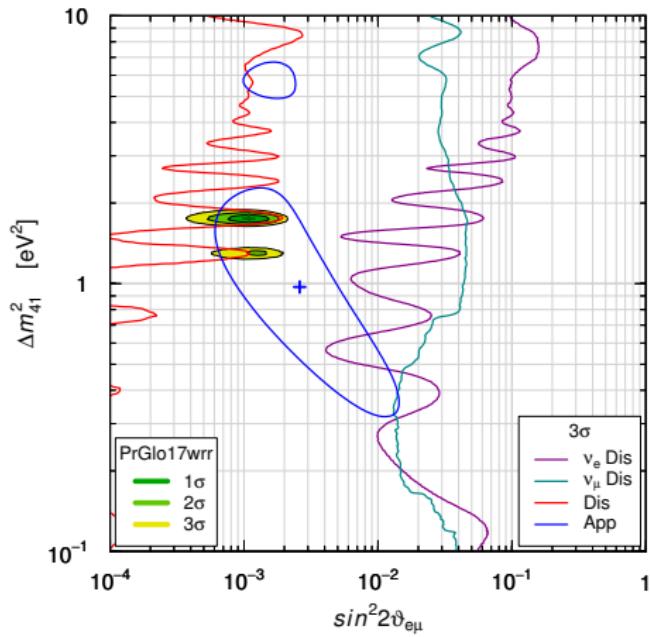

[Daya Bay, arXiv:1508.04233]

- ▶ Cannot be explained by neutrino oscillations (SBL oscillations are averaged in Double Chooz, Daya Bay, RENO).
- ▶ Very likely due to theoretical miscalculation of the spectrum.
- ▶ $\sim 3\%$ effect on total flux, but if it is an excess it increases the anomaly!
- ▶ No post-bump complete calculation of the neutrino fluxes.
- ▶ Saclay-Huber flux calculation uncertainty is about 2.5%.
- ▶ Increasing the flux uncertainty is a game that one can play, but there are only guesses, e.g. about 5%.
[Hayes and Vogel, 2016]
- ▶ Better to exclude the reactor rates from the global fit. [suggestion of Pedro Machado at WIN 2017]

Global Fit

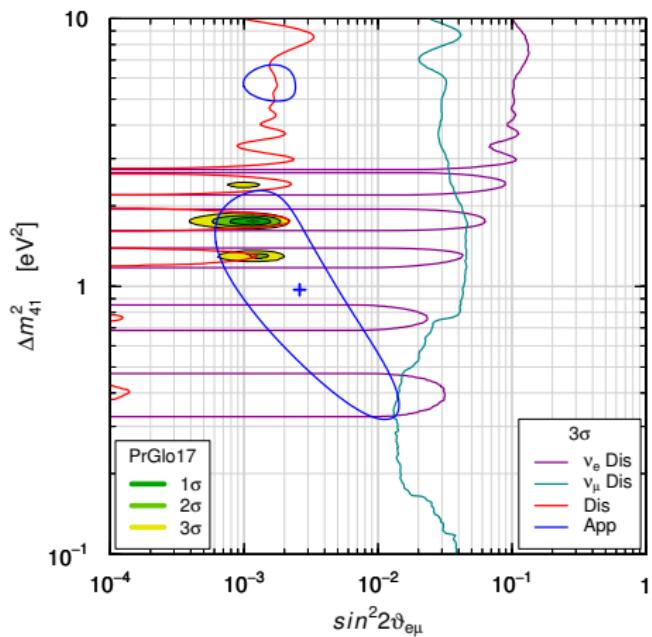

Without Reactor Rates

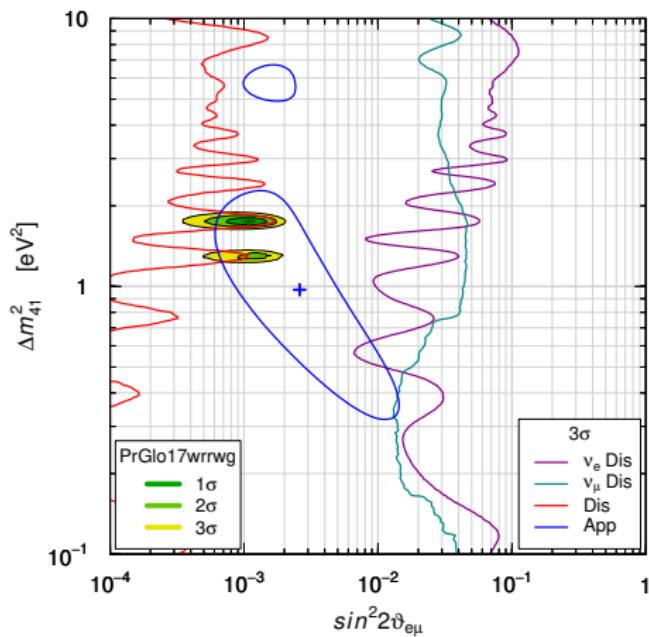

The Reactor Antineutrino Anomaly has small impact on the global fit.

Global Fit

Without Reactor Rates and Gallium Data

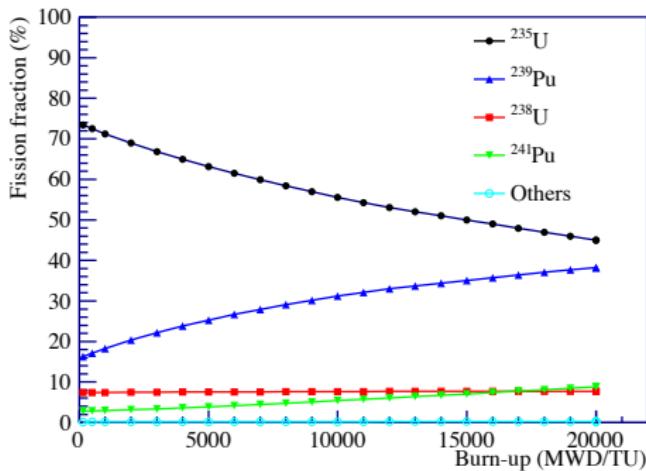

Given the current constraints, only the LSND signal is crucial for a positive indication in favor of active-sterile SBL oscillations.

Daya Bay Reactor Fuel Evolution

[Daya Bay, arXiv:1704.01082]

[Tsang @ EPS-HEP 2017]

- Reactor $\bar{\nu}_e$ flux produced by the β decays of the fission products of ^{235}U , ^{238}U , ^{239}Pu , ^{241}Pu .

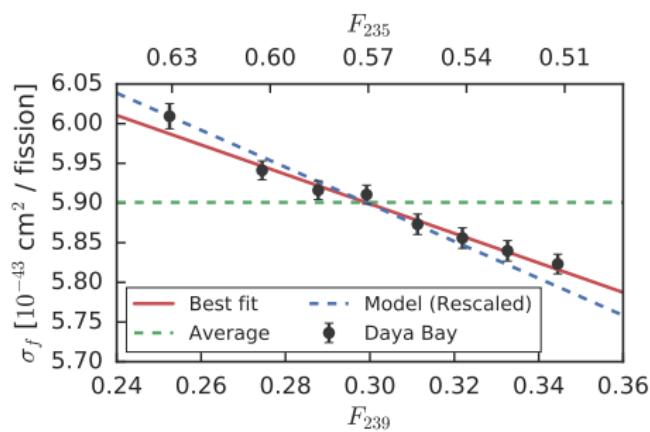

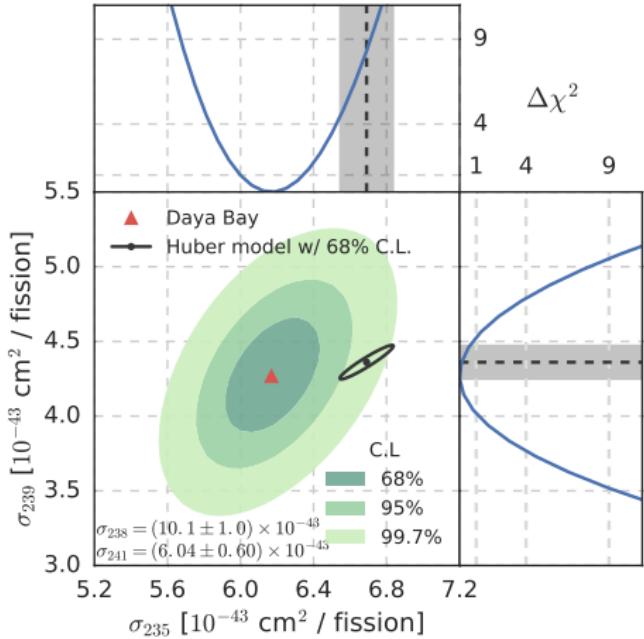

- Cross section per fission:

$$\sigma_f = \sum_{i=235,238,239,241} F_i \sigma_{f,i}$$

- Effective fission fractions:

$$F_{235}, F_{238}, F_{239}, F_{241}.$$

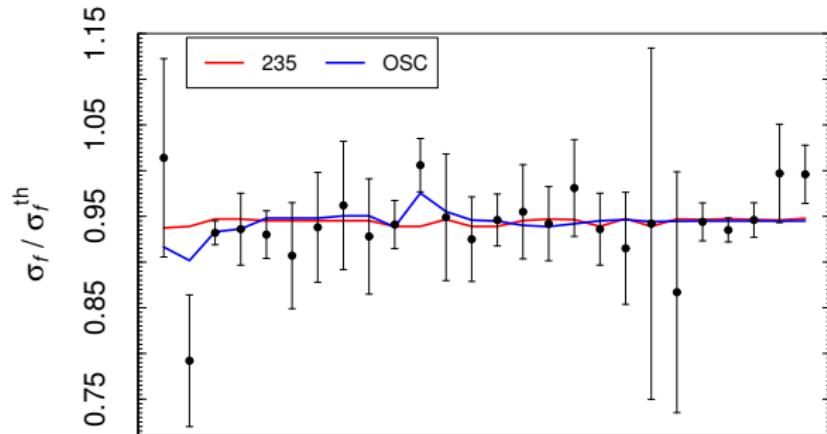

- ▶ Best fit: suppression of $\sigma_{f,235}$.
- ▶ Equal fluxes suppression:
 $\Delta\chi^2/\text{NDF} = 7.9/1$
 disfavored at 2.8σ .
- ▶ Equal fluxes suppression corresponds to SBL oscillations, but theoretical flux uncertainties must be taken into account.

With theoretical flux
uncertainties:

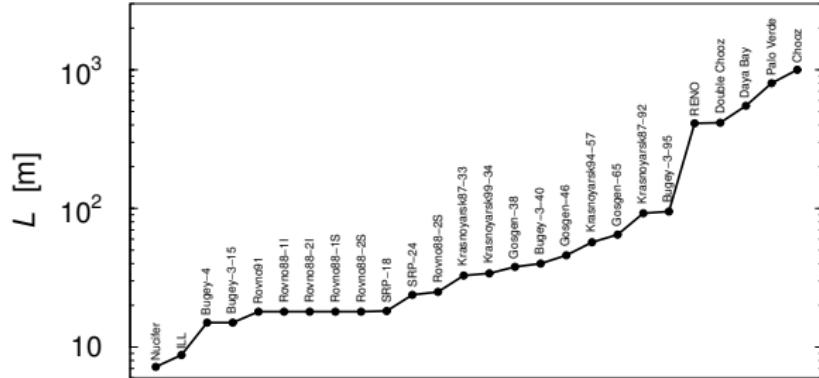

| Daya Bay | ^{235}U | OSC |
|-----------------|------------------|-----|
| χ^2_{\min} | 4.6 | 9.6 |
| NDF | 7 | 7 |
| GoF | 71% | 21% |

MC: OSC disfavored at 2.5σ

| All Reactors | ^{235}U | OSC |
|-----------------|------------------|------|
| χ^2_{\min} | 29.4 | 28.7 |
| NDF | 32 | 31 |
| GoF | 60% | 58% |

MC: ^{235}U disfavored at 1.5σ

Conclusions

- ▶ Exciting indications of sterile neutrinos (new physics!) at the eV scale:
 - ▶ LSND $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ signal (caveat: single experimental signal).
 - ▶ Gallium ν_e disappearance (caveat: overestimated detector efficiency?).
 - ▶ Reactor $\bar{\nu}_e$ disappearance (caveat: flux calculation dependence).
- ▶ Vigorous experimental program to check **conclusively** in a few years:
 - ▶ ν_e and $\bar{\nu}_e$ disappearance with reactors and radioactive sources.
 - ▶ $\nu_\mu \rightarrow \nu_e$ transitions with accelerator neutrinos.
 - ▶ ν_μ disappearance with accelerator neutrinos.
- ▶ Independent tests through effect of m_4 in β -decay and $\beta\beta_{0\nu}$ -decay.
- ▶ Cosmology: strong tension with $\Delta N_{\text{eff}} = 1$ and $m_4 \approx 1 \text{ eV}$. It may be solved by a non-standard cosmological mechanism.
- ▶ Possibilities for the next years:
 - ▶ Reactor and source experiments ν_e and $\bar{\nu}_e$ observe SBL oscillations: big excitement and explosion of the field.
 - ▶ Otherwise: still marginal interest to check the LSND appearance signal.
 - ▶ In any case the possibility of the existence of sterile neutrinos related to New Physics beyond the Standard Model will continue to be studied (e.g keV sterile neutrinos).
